

# EVALUATING ENERGY-EFFICIENCY USING THERMAL IMAGING

Huber Flores, Jonatan Hamberg, Xin Li, Titti Malmivirta,  
Agustin Zuniga, Eemil Lagerspetz, Petteri Nurmi

# MOTIVATION

***How to evaluate energy footprint of apps  
on emerging IoT / wearable / mobile  
devices?***

- No direct access to power source
- Difficult to separate overall power draw vs power consumed by software

# CURRENT SOLUTIONS

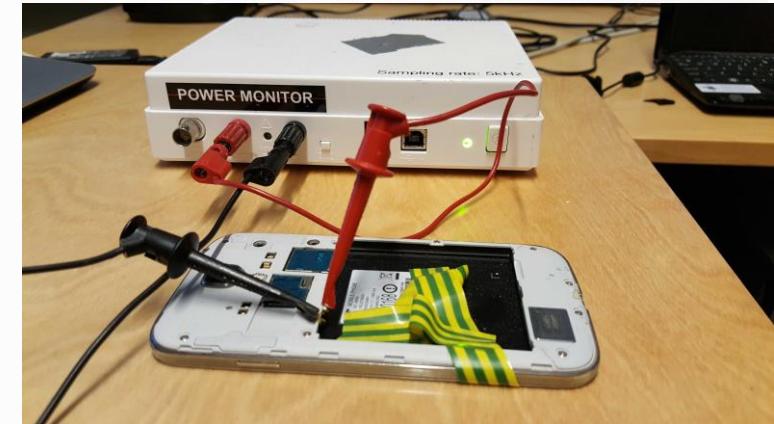

## Hardware power monitors

- Highly accurate for instantaneous power consumption
- Require connection between power source and device (detachable battery / power source)
- Bulky and limited to fixed contexts

## Power profiling

- Mathematical models of energy, can be constructed through software or hardware sampling
- Vulnerable to biases (testbed, sampling method, measurement context, ...)
- Limited generality and better at relative than absolute estimates

# THERMAL IMAGING

- Off-the-shelf devices with thermal cameras increasingly available
  - Smartphones: Caterpillar S60 and S61
  - Attachable: FLIR One range of thermal cameras
- Relies on *forward looking infrared (FLIR)*
  - Measures thermal radiation, not temperature
  - Off-the-shelf devices *uncooled* making them sensitive to heating of the device

# THERMAL ENERGY-EFFICIENCY

- General idea simple: take thermal image of device running an app and convert that into an energy estimate
- Conversion from thermal energy to power governed by Stefan-Boltzmann law:  $P = \varepsilon\sigma AT^4$ 
  - $A$  = surface area
  - $\varepsilon$  = emissivity of material
  - $\sigma$  = Bolzmann constant

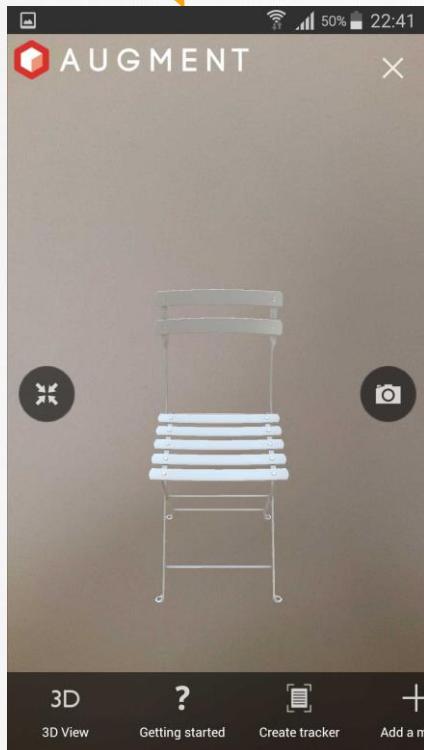

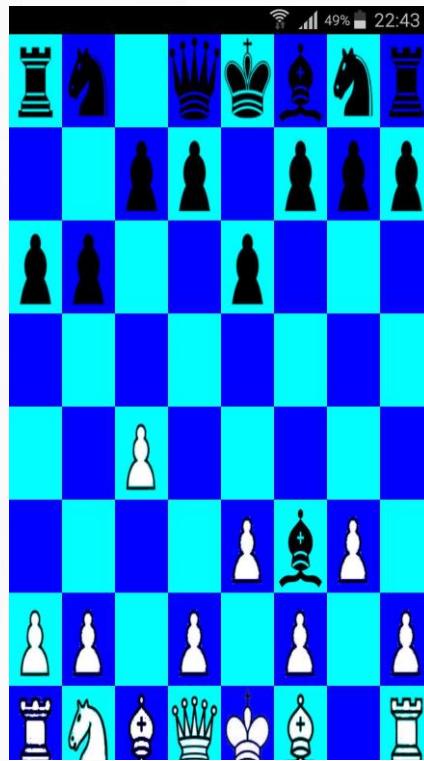

# SOUNDS HOT, DOES IT ACTUALLY WORK?

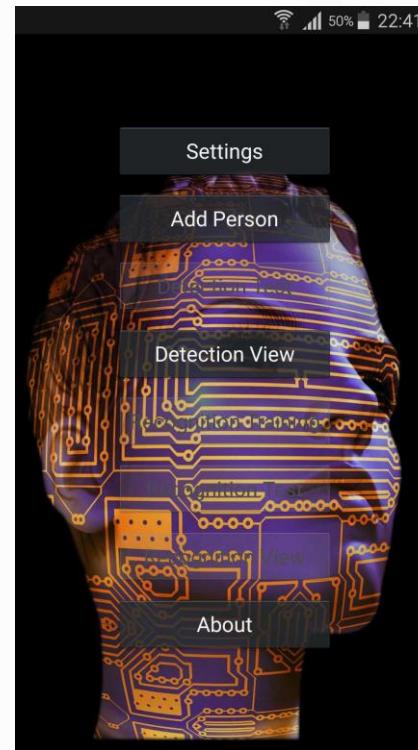

# EXPERIMENTAL SETUP

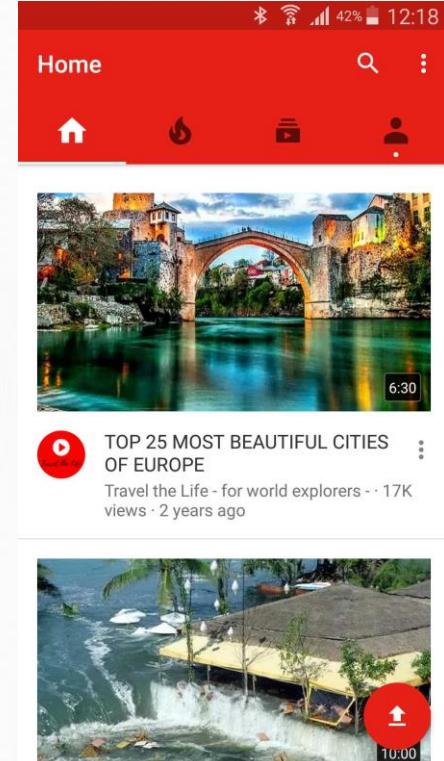

**Augment.** augmented reality application that allows manipulating and viewing virtual objects

**Chess:** puzzle game that allows playing against a computer opponent (minimax algorithm)

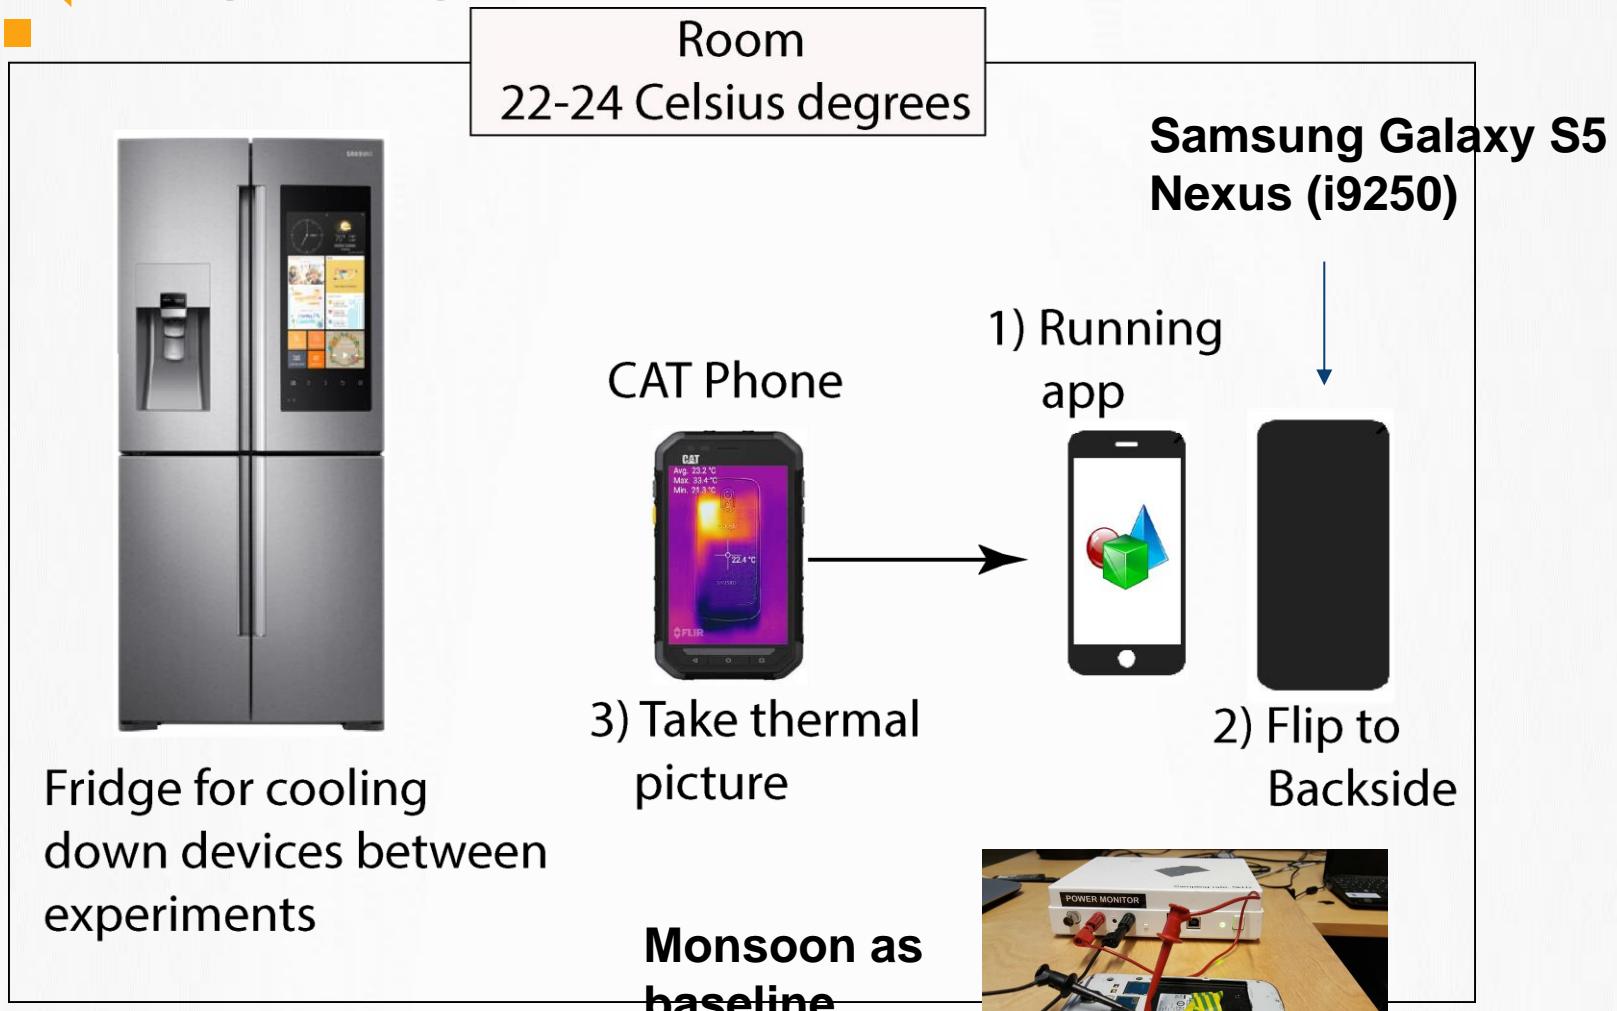

**Face:** application that allows device to identify a person based on facial recognition

**YouTube:** used for separate discharge experiments

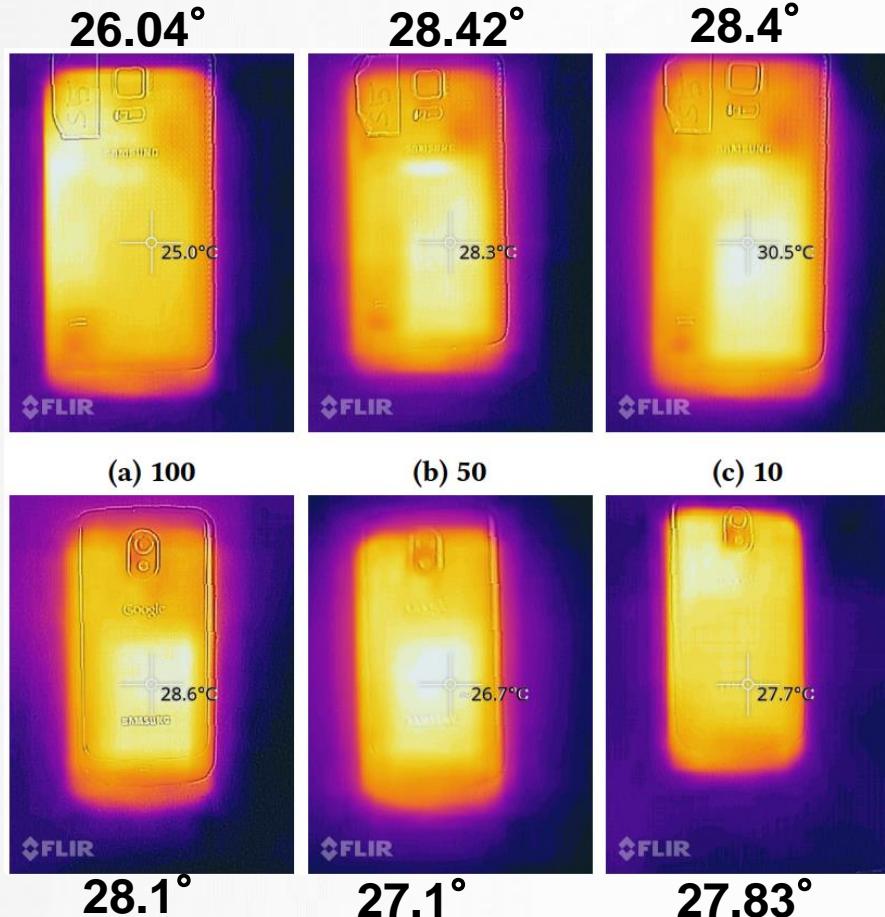

# EXPERIMENTAL SETUP

# RESULTS: FEASIBILITY ANALYSIS

**Experiment Setup:**  
Discharge experiment where constant charge (YouTube) applied until device empty

**Results:** avg. temperature difference  $0.77^\circ$  across all battery levels

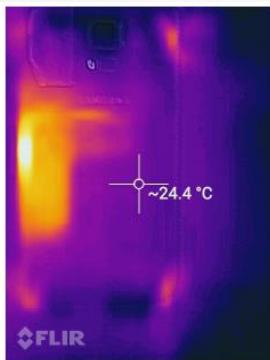

→ Thermal footprint is sufficiently stable over time when load is constant

# RESULTS: ENERGY FOOTPRINT

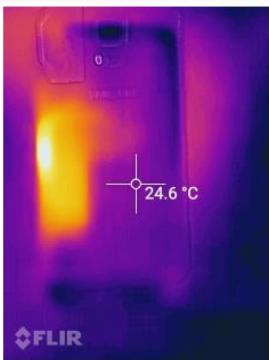

$\Delta 1.25^\circ$

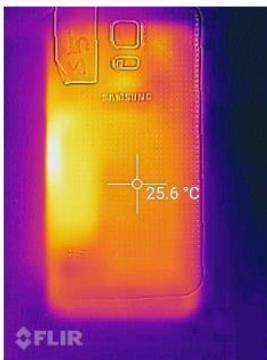

(a) Chess

$\Delta 1.41^\circ$

(b) Face

$\Delta 1.47^\circ$

(c) Augment

(d) Chess

(e) Face

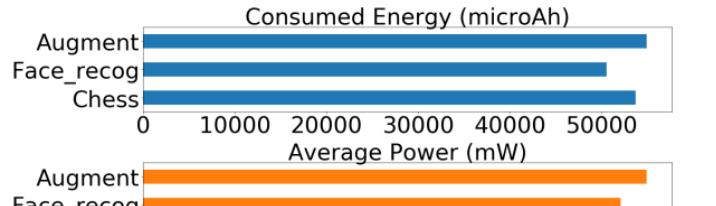

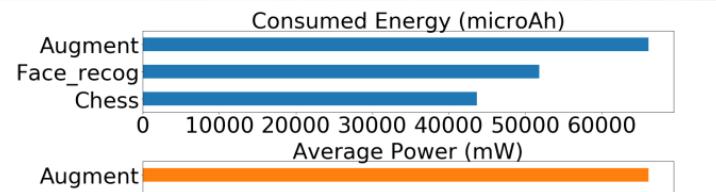

(f) Augment

$\Delta 1.82^\circ$

$\Delta 1.26^\circ$

$\Delta 2.07^\circ$

# CHALLENGES: ABSOLUTE ESTIMATES

	Augment	Face	Chess
<b>Monsoon S5</b>	3138.93	2509.74	2067.50
<b>Thermal S5</b>	15544.51	14654.03	14917.53

- Absolute estimates sensitive to accuracy of emissivity and surface area estimates
- Relative estimates for *same* device insensitive against inaccuracies in these estimates

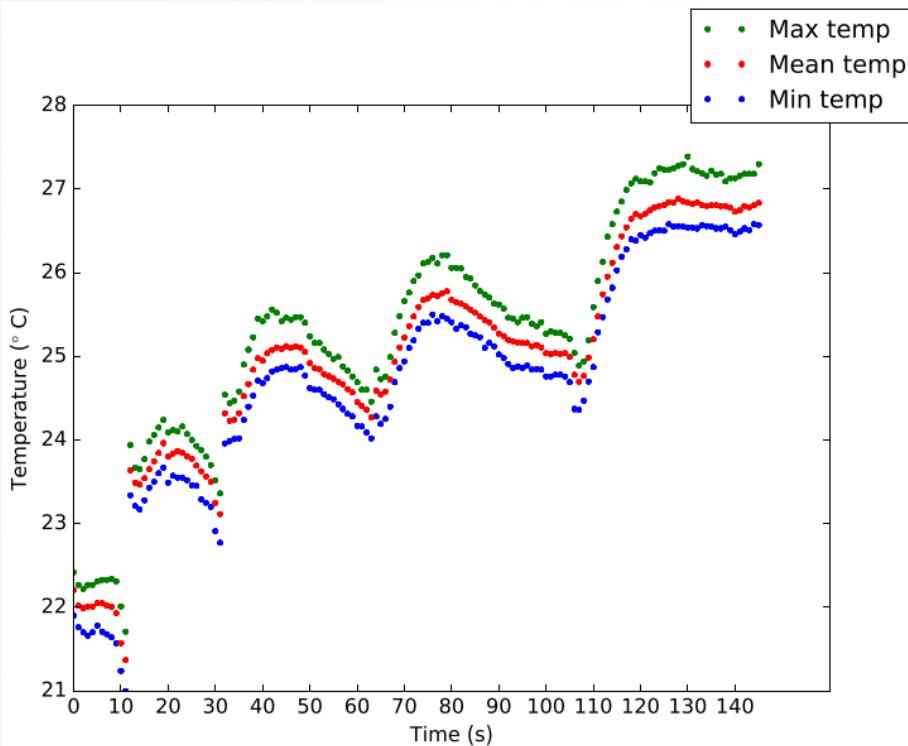

# CHALLENGES: MEASUREMENT AREA

- Thermal footprint varies across apps depending on which components they utilize
- Accurate thermal estimation requires region-based thermal estimates that take into account different system components

# CHALLENGES: CALIBRATION

- In *continuous* monitoring, accuracy of thermal imaging suffers due to heat seeping to the thermal sensor
- Errors can be mitigated through calibration
- Our experiments used individual images to avoid issues from heating of thermal sensor

***"Hot or Not? Robust and Accurate Continuous Thermal Imaging on FLIR cameras"***, T. Malmivirta, J. Hamberg, E. Lagerspetz, X. Li, E. Peltonen, H. Flores, P. Nurmi, PerCom 2019

# DISCUSSION

## Challenges

- Higher accuracy requires potentially images from multiple different angles / viewpoints (e.g., front screen vs. backside)
- Thermal output depends on *surface emissivity* of material that is being monitored
- Heat conduction from internal and external sources affect thermal energy transfer

## Advantages

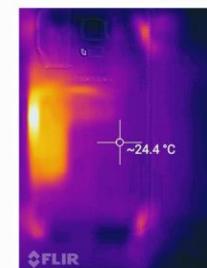

- Independent of power source and charging/discharging state of device being monitored
- Applicable without access to battery / power source
- Can operate in different contexts

# SUMMARY

- Introduced a novel approach for estimating *relative* energy footprint of IoT devices using thermal imaging
- Demonstrated feasibility of our idea through benchmark experiments
  - Thermal footprint stable for constant operating load
  - Thermal footprint differs across apps with different intensity levels
  - Relative differences in footprint match with power monitor results

# Thank you!
